## General

Get help for a specific function:

<b>Matlab</b>	<code>help sqrt</code>
<b>Torch</b>	<code>help(torch.sqrt)</code>

## Matrices and Tensors

Create a two-dimensional tensor or matrix:

<b>Matlab</b>	<code>m = [9, 6, 3, 4; 7, 2, 8, 1]</code>
<b>Torch</b>	<code>m = torch.Tensor({{9, 6, 3, 4}, {7, 2, 8, 1}})</code>

Create a row vector:

<b>Matlab</b>	<code>v = [9, 7, 6, 8]</code> or <code>v = [9 7 6 8]</code>
<b>Torch</b>	<code>v = torch.Tensor({{9, 7, 6, 8}})</code>

But, this is not used as a vector in Torch because it is still a two-dimensional Tensor.

Create a column vector:

<b>Matlab</b>	<code>v = [9; 7; 6; 8]</code>
<b>Torch</b>	<code>v = torch.Tensor({{9}, {7}, {6}, {8}})</code>

But, this is not used as a vector in Torch because it is still a two-dimensional Tensor.

Create a one-dimensional tensor:

<b>Matlab</b>	<i>Not available</i>
<b>Torch</b>	<code>t = torch.Tensor({9, 7, 6, 8})</code>

Matlab does not have *one-dimensional tensors*; this can be verified by running `ndims([9, 7, 6, 8])`. On the other hand, for many operations that Matlab uses row or column vectors, Torch uses a one-dimensional tensor.

Access an element in a vector or one-dimensional tensor:

<b>Matlab</b>	<code>v(2)</code>
<b>Torch</b>	<code>t[2]</code>

Second element of the vector is accessed.

---

\*Matlab<sup>®</sup> is a registered trademark of The MathWorks, Inc.

### Access an element from the end of a vector or one-dimensional tensor:

<b>Matlab</b>	<code>v(end-1)</code>
<b>Torch</b>	<code>t[-2]</code>

Second element from the end of the vector is accessed.

### Access a range of elements in a vector or one-dimensional tensor:

<b>Matlab</b>	<code>v(2:4)</code>
<b>Torch</b>	<code>t[{2,4}]</code>

Second to fourth elements of the vector are accessed.

### Access an element in a Matrix:

<b>Matlab</b>	<code>m(2,3)</code>
<b>Torch</b>	<code>m[{2,3}]</code> or <code>m[2][3]</code>

In both cases, second row, third column element is accessed.

### Access a row in a Matrix as a two-dimensional tensor:

<b>Matlab</b>	<code>m(2,:)</code>
<b>Torch</b>	<code>m[{2},{}]</code>

The returned row is a two-dimensional tensor.

### Access a row in a Matrix as a one-dimensional tensor:

<b>Matlab</b>	<i>Not available</i>
<b>Torch</b>	<code>m[{2},{}]</code> or <code>m[2]</code>

The returned row is a one-dimensional tensor.

### Access a column in a Matrix as a two-dimensional tensor:

<b>Matlab</b>	<code>m(:,2)</code>
<b>Torch</b>	<code>m[{},{2}]</code>

The returned column is a two-dimensional tensor.

### Access a column in a Matrix as a one-dimensional tensor:

<b>Matlab</b>	<i>Not available</i>
<b>Torch</b>	<code>m[{},{2}]</code>

The returned column is a one-dimensional tensor.

### Access a range of elements in a Matrix:

<b>Matlab</b>	<code>m(2,2:4)</code>
<b>Torch</b>	<code>m[{2},{2,4}]</code> or <code>m[{2},{2,4}]</code>

The second to fourth columns of the second row are returned. In Torch, there is a slight difference between using `index` (e.g. 2) or `{index}` (e.g. {2}) for pointing to a singleton dimension. For `{index}`, the dimension of the returned tensor is same as the original tensor (e.g. tensor `m`). For `index`, the singleton dimension is removed, and the dimension of the returned tensor is one less than the original tensor (e.g. tensor `m`). Also, `{}` refers to all elements in that dimension. Finally, `-index` means `index`-th element from the end.

## Forming Basic Tensors

Create a tensor over a range of values with step 1:

<b>Matlab</b>	<code>3:8</code>
<b>Torch</b>	<code>torch.range(3,8)</code>

Torch's result is a one-dimensional tensor.

Create a tensor over a range of values with an arbitrary step:

<b>Matlab</b>	<code>3:-1.9:-4.2</code>
<b>Torch</b>	<code>torch.range(3,-4.2,-1.9)</code>

Torch's result is a one-dimensional tensor.
